Validate ICON and pol. forward operator EMVORADO with C-band radars

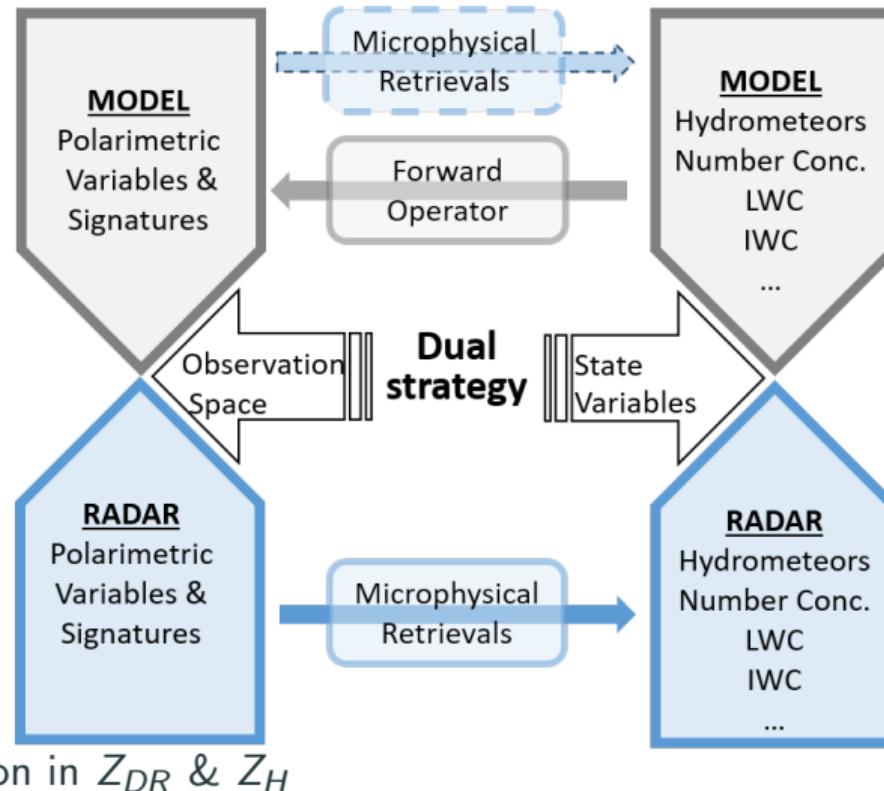

Validate ICON and pol. forward operator EMVORADO with C-band radars

→ settings of ICON

→ parameters for
EMVORADO

DWD C-band network

- correct ρ_{HV}
- calc. Φ_{DP} offset
- smooth K_{DP}
- calibrate Z_{DR}
- correct for attenuation in Z_{DR} & Z_H

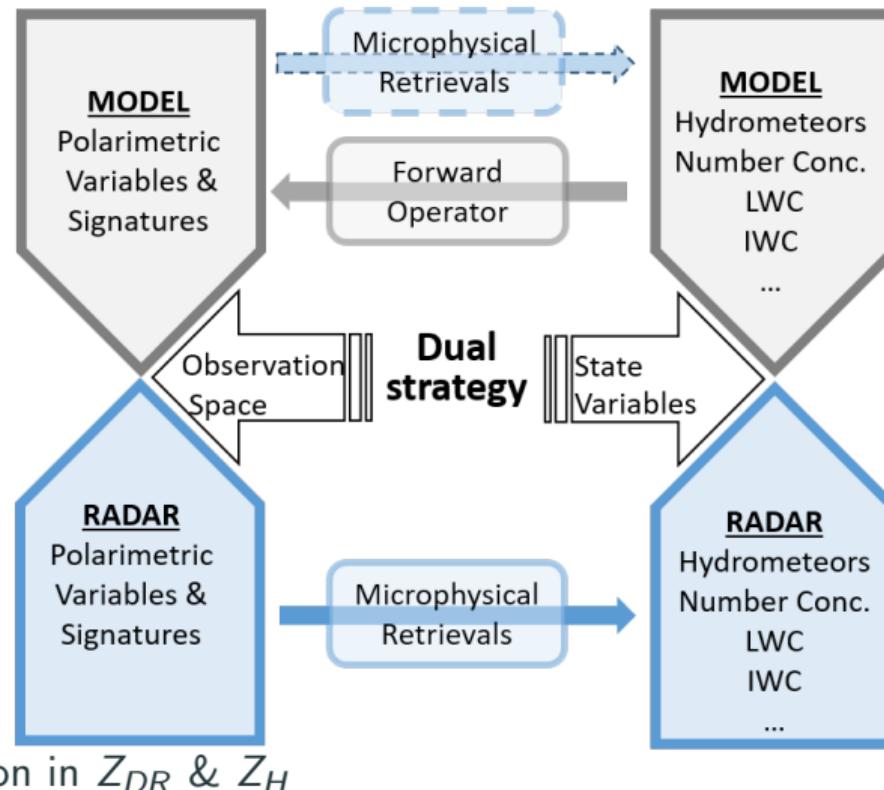

Validate ICON and pol. forward operator EMVORADO with C-band radars

→ settings of ICON

→ parameters for
EMVORADO

DWD C-band network

→ correct ρ_{HV}
→ calc. Φ_{DP} offset
→ smooth K_{DP}
→ calibrate Z_{DR}
→ correct for attenuation in Z_{DR} & Z_H

OP HM I:

10 stratiform cases:
→ 25-07-2017
...

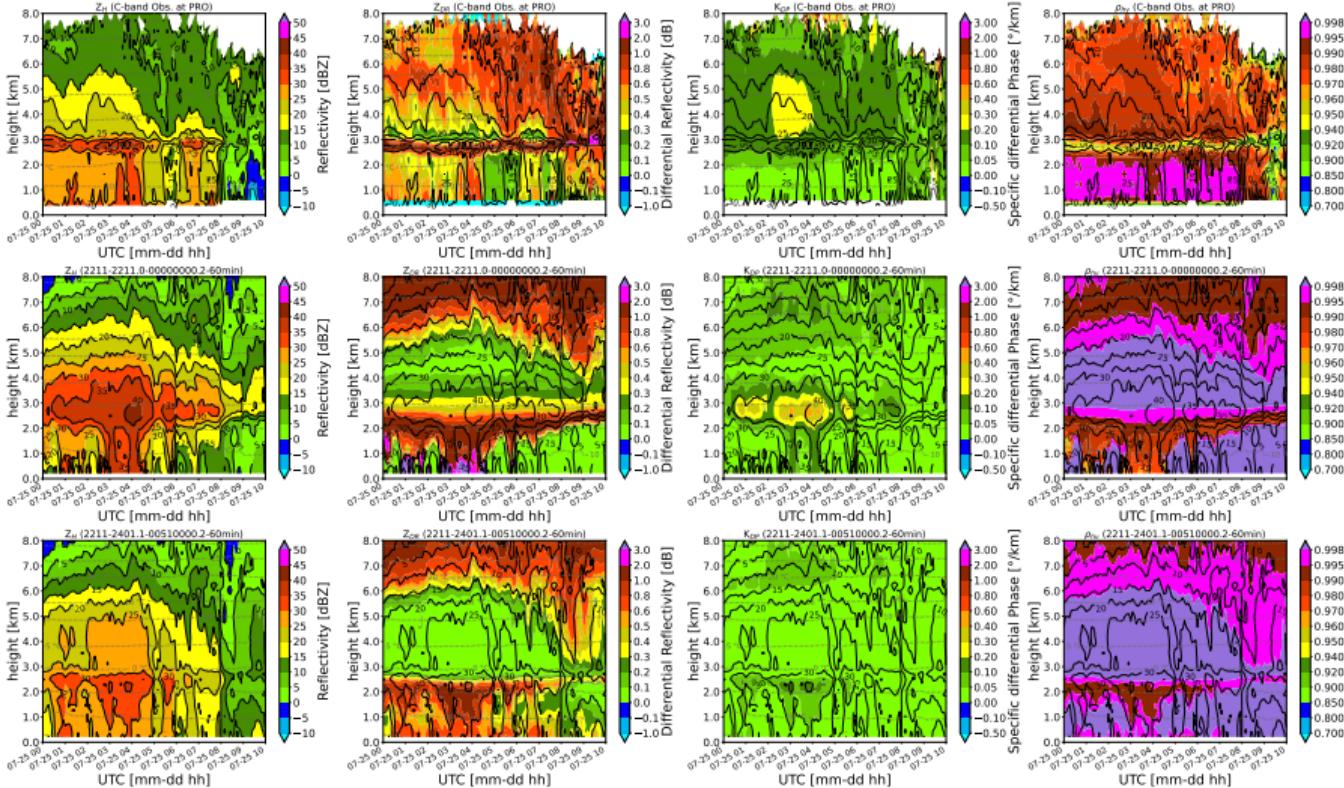

OP HM II

(250 m resol.):
2 stratiform cases:
→ 14-07-2021
...

8 convective cases:
→ 20-05-2022
...

OP HM I: 25-07-2017

QVPs(12°) for PRO on 25-07-2017 00:00-09:55 for stratiform PPIs

Observation

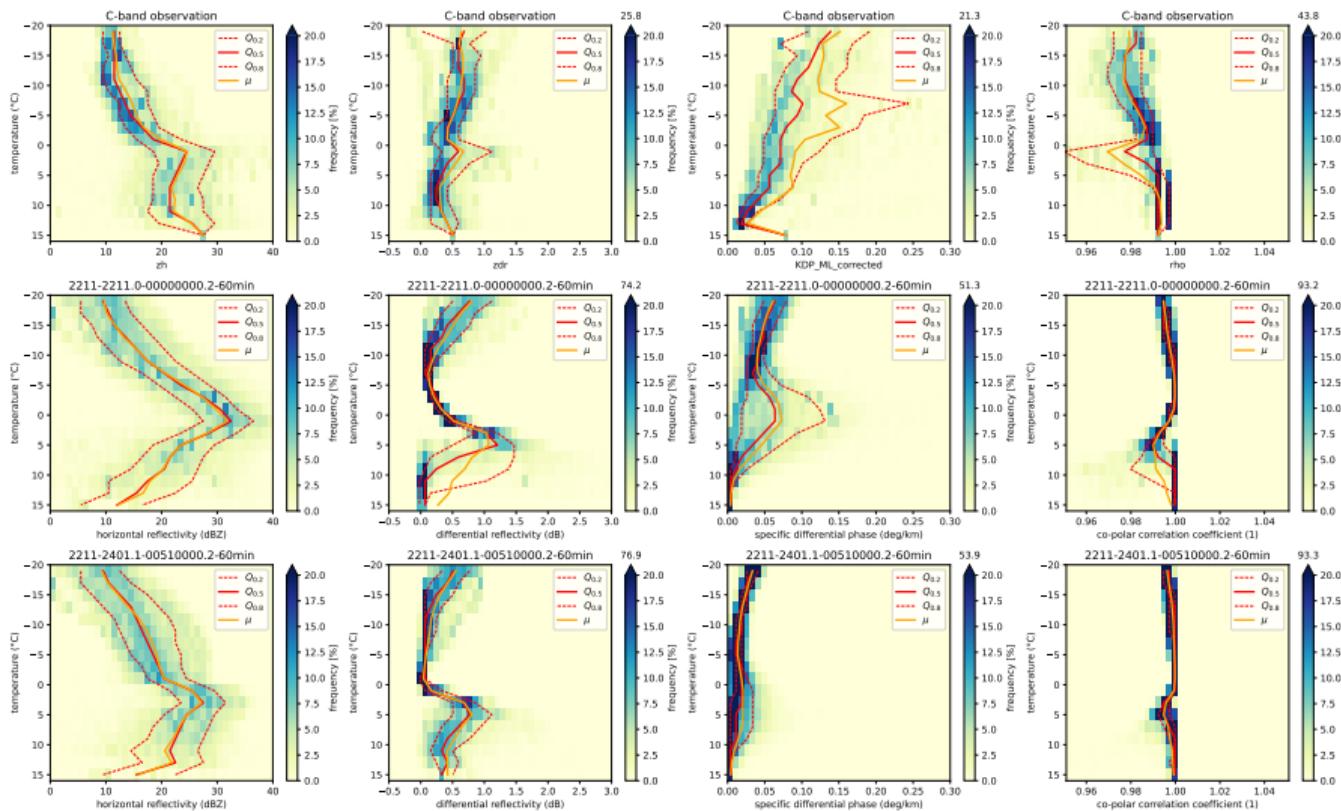

'Bringi-book run'

- no sharp ML
- too high Z_{DR} below ML
- long surviving graupel

'state-of-our-art run'

- finer ML
- more realistic Z_{DR}

CFTDs(12°) for all DWD radars on 25-07-2017 00:00-23:55 for stratiform PPIs

Observation

'Bringi-book run'

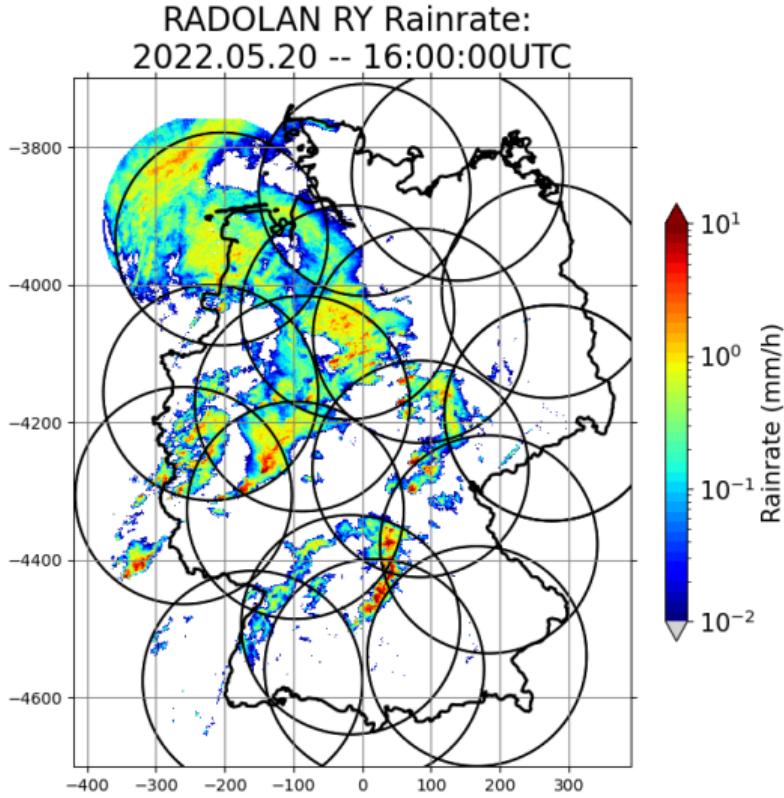

- broad ML
- high Z_{DR} spread below ML

'state-of-our-art run'

- finer ML
- realistic Z_{DR} spread

OP HM II: 20-05-2022

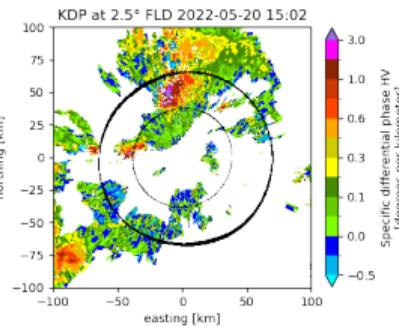

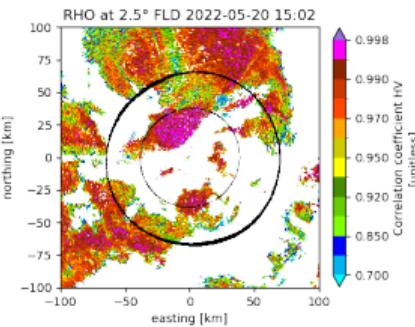

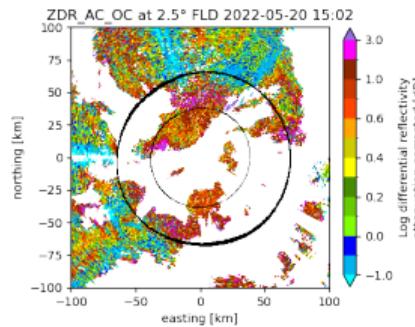

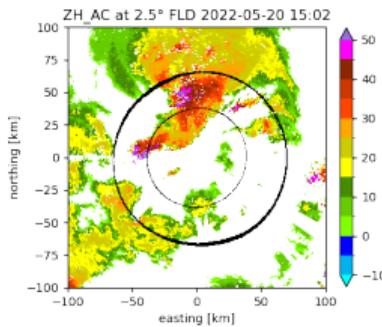

RADOLAN RY for on 20-05-2022 15:00 - 15:55

- convective day with many storms

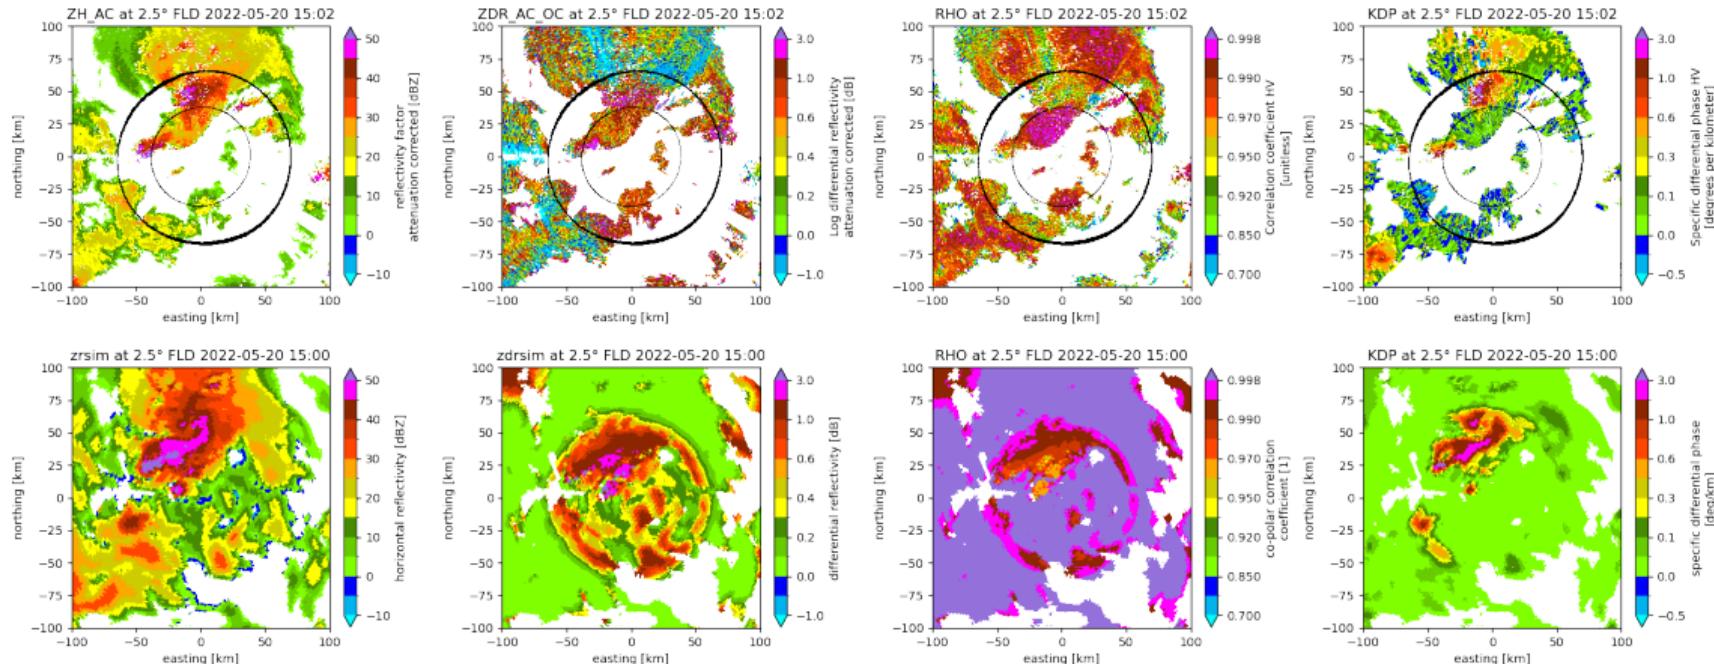

5 tornadoes in Germany:
→ 15:00 UTC in Paderborn
(FLD radar)

PPI (2.5°) for FLD on 20-05-2022 15:00

→ obs with strong attenuation

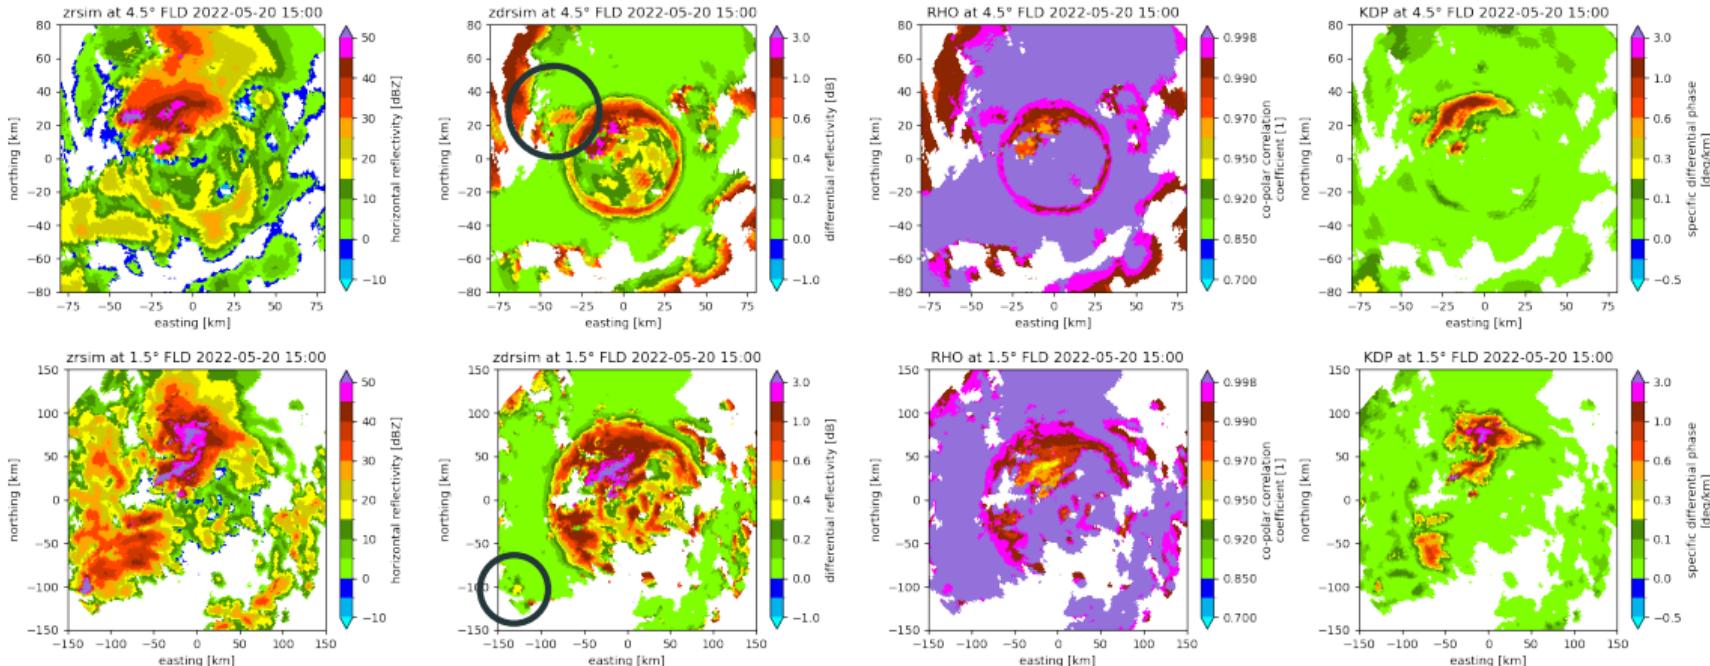

PPI (2.5°) for FLD on 20-05-2022 15:00

→ obs with strong attenuation

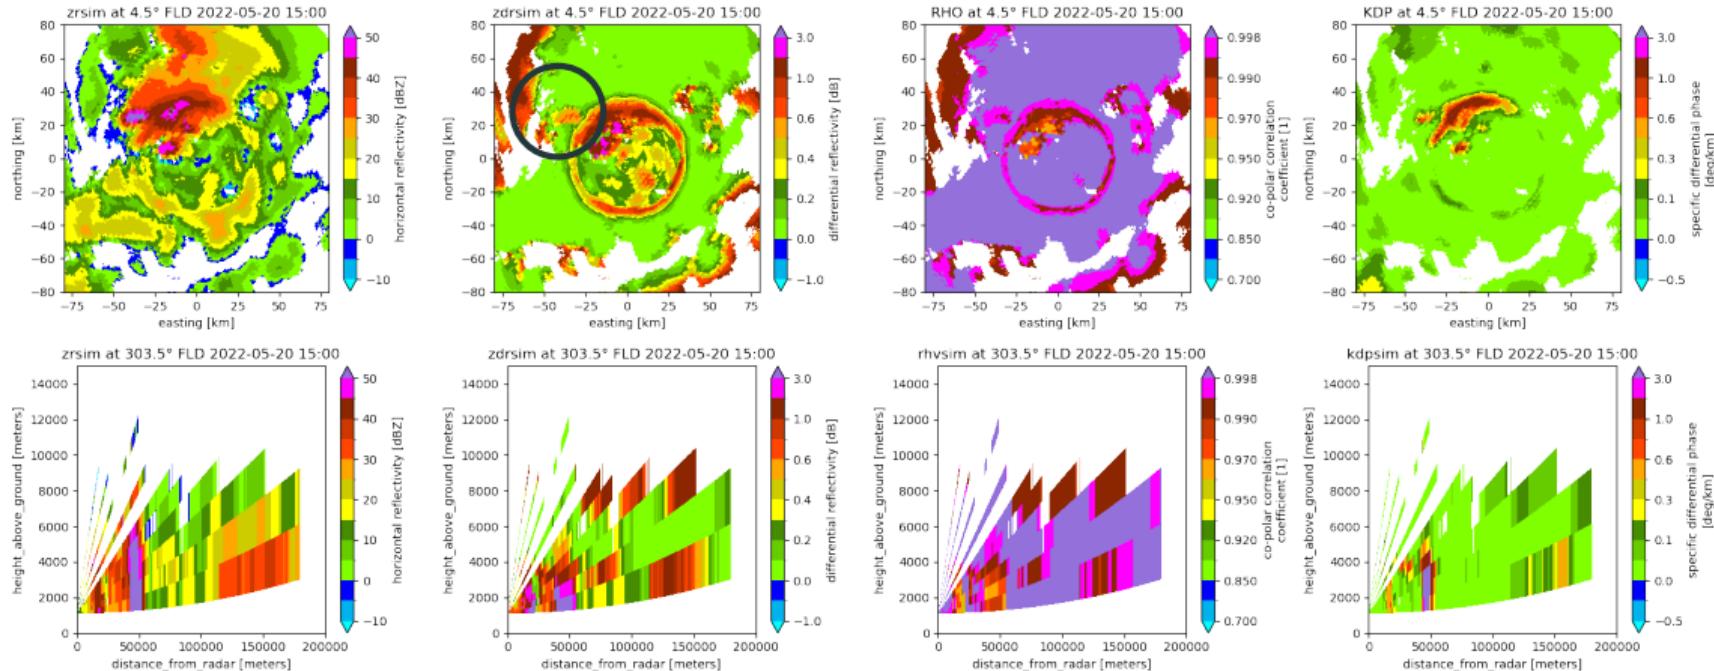

→ mod with broader rain field

PPIs (4.5° , 1.5°) for FLD on 20-05-2022 15:00 with Z_{DR} columns

However: two Z_{DR} columns apparent (C1, C2)
(high Z_{DR} above ML in convective situation indicates uplifted rain) 7

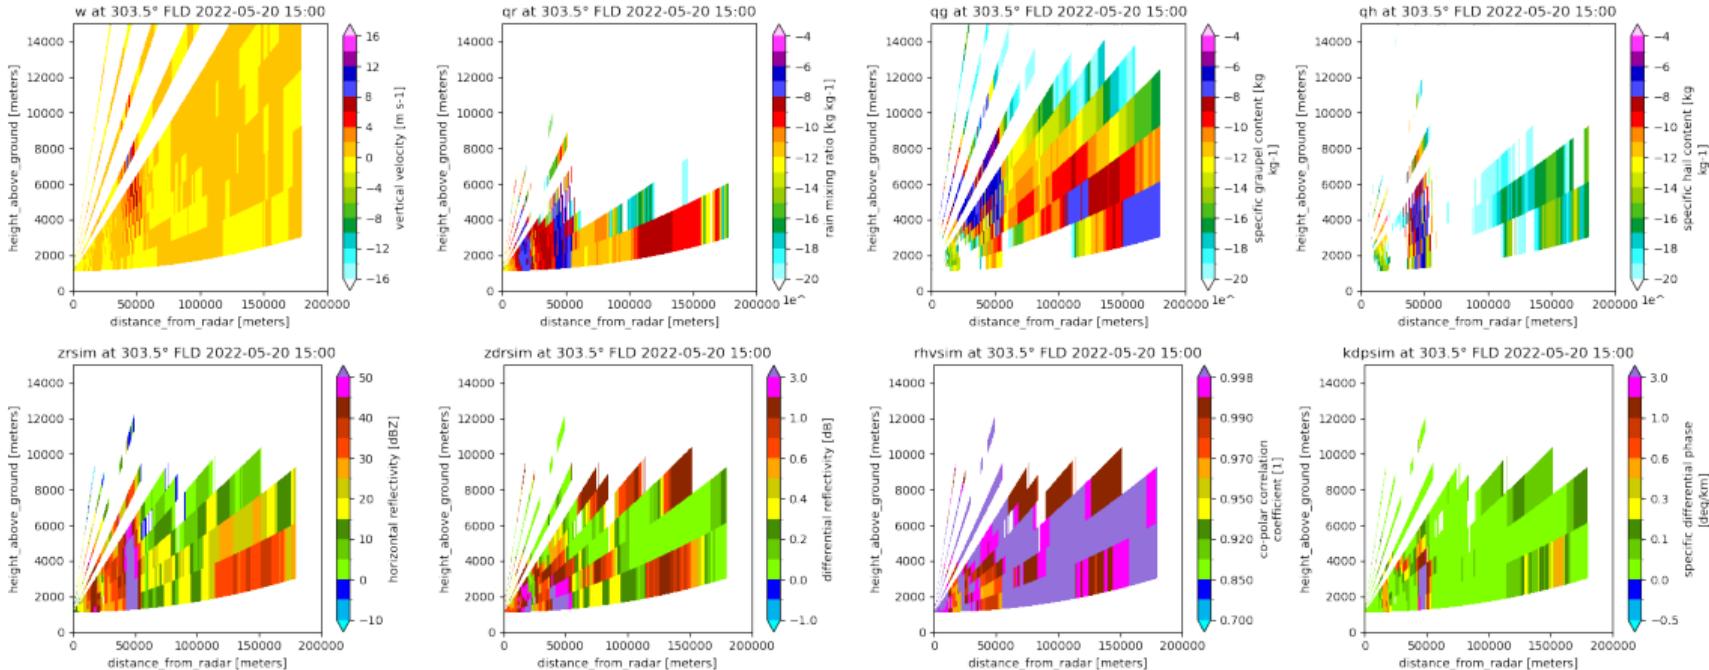

C1: PPIs (4.5°) and pseudoRHIs (303.5°) for FLD on 20-05-2022 15:00

→ high values of Z_H in all levels

→ vertical extend of high values in other moments smaller

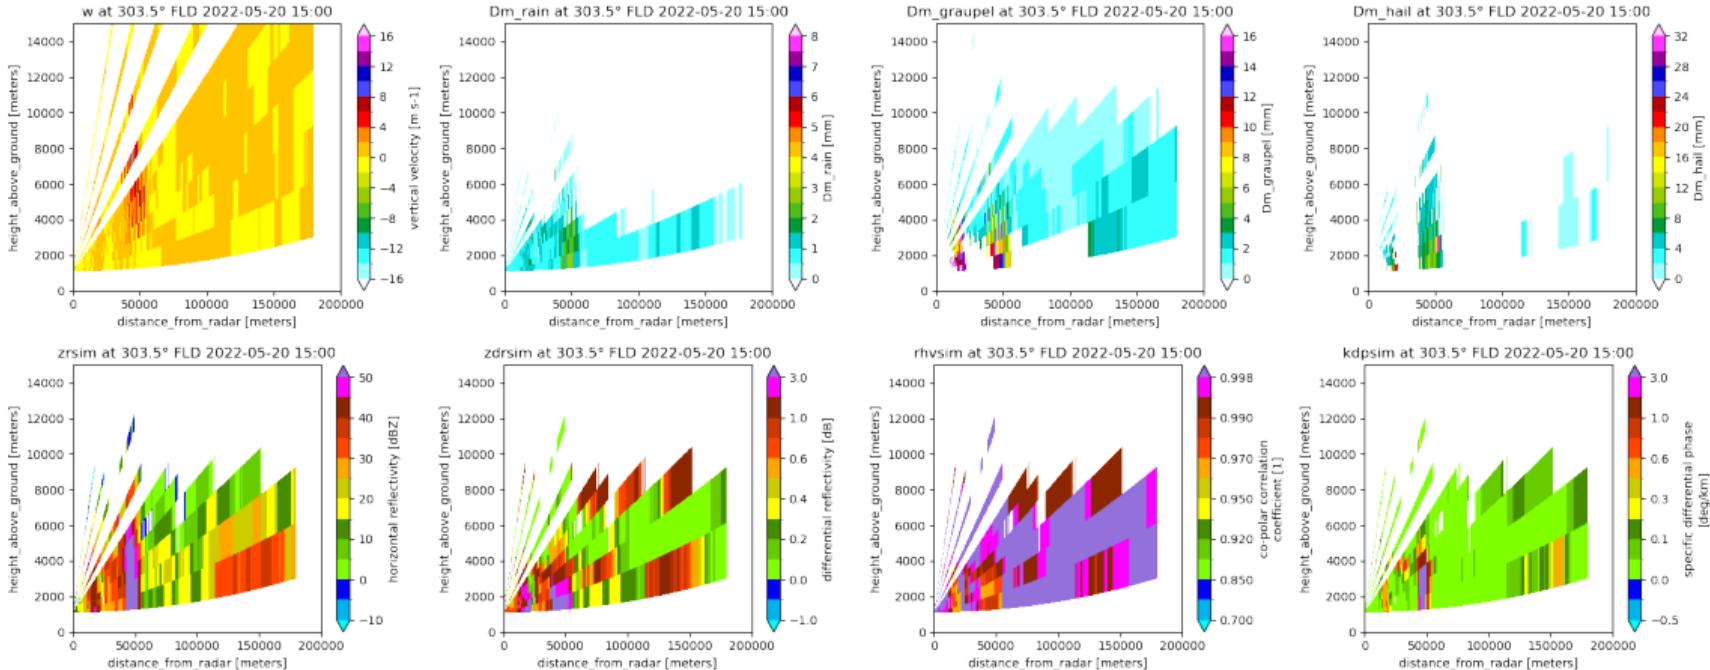

C1: pseudoRHIs (303.5°) with w, qr, qg, qh for FLD on 20-05-2022 15:00

→ core updraft of $w \sim 10 \text{ m/s}$

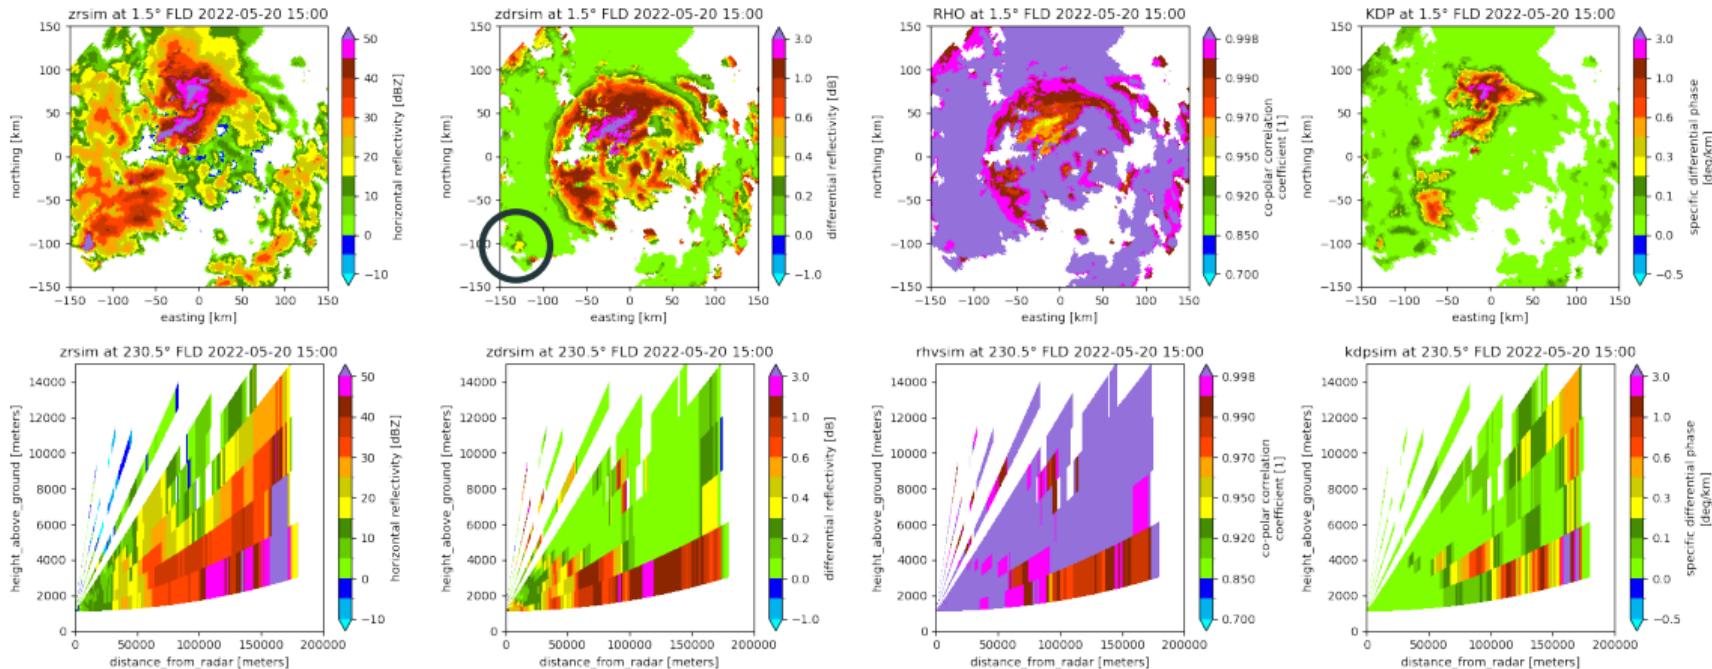

→ specific contents for rain, graupel, and hail are high

C1: pseudoRHIs (303.5°) with median volume diameters of r, g, and h

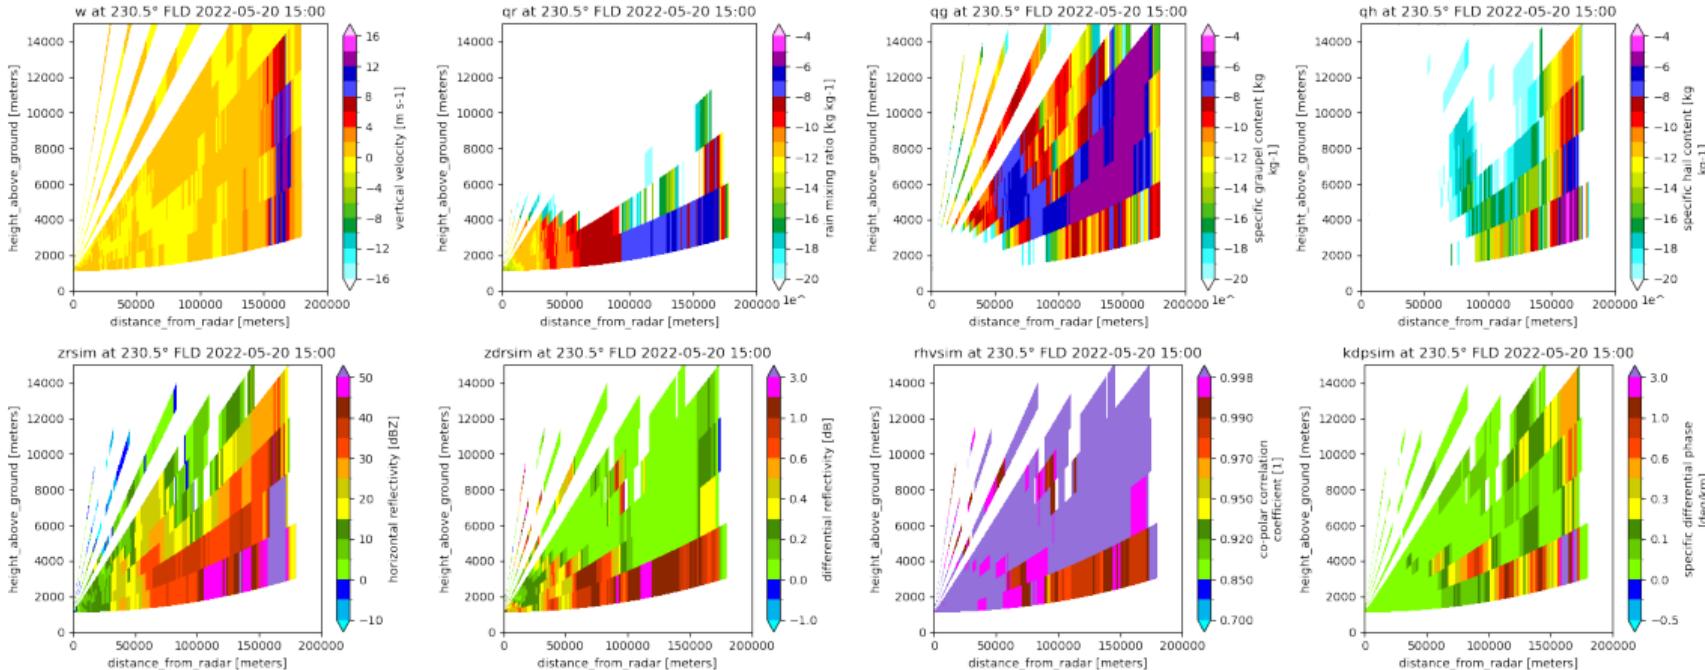

→ raindrops ~ 1 mm are too small for producing significant Z_{DR}
 → hail ~ 5 mm dominates signal

C2: PPIs (4.5°) and pseudoRHIs (230.5°) for FLD on 20-05-2022 15:00

→ C2 higher than C1 (~ 12 km) with Z_H , Z_{DR} , and ρ_{HV} similar structure
 → enhanced K_{DP} values in 12 km

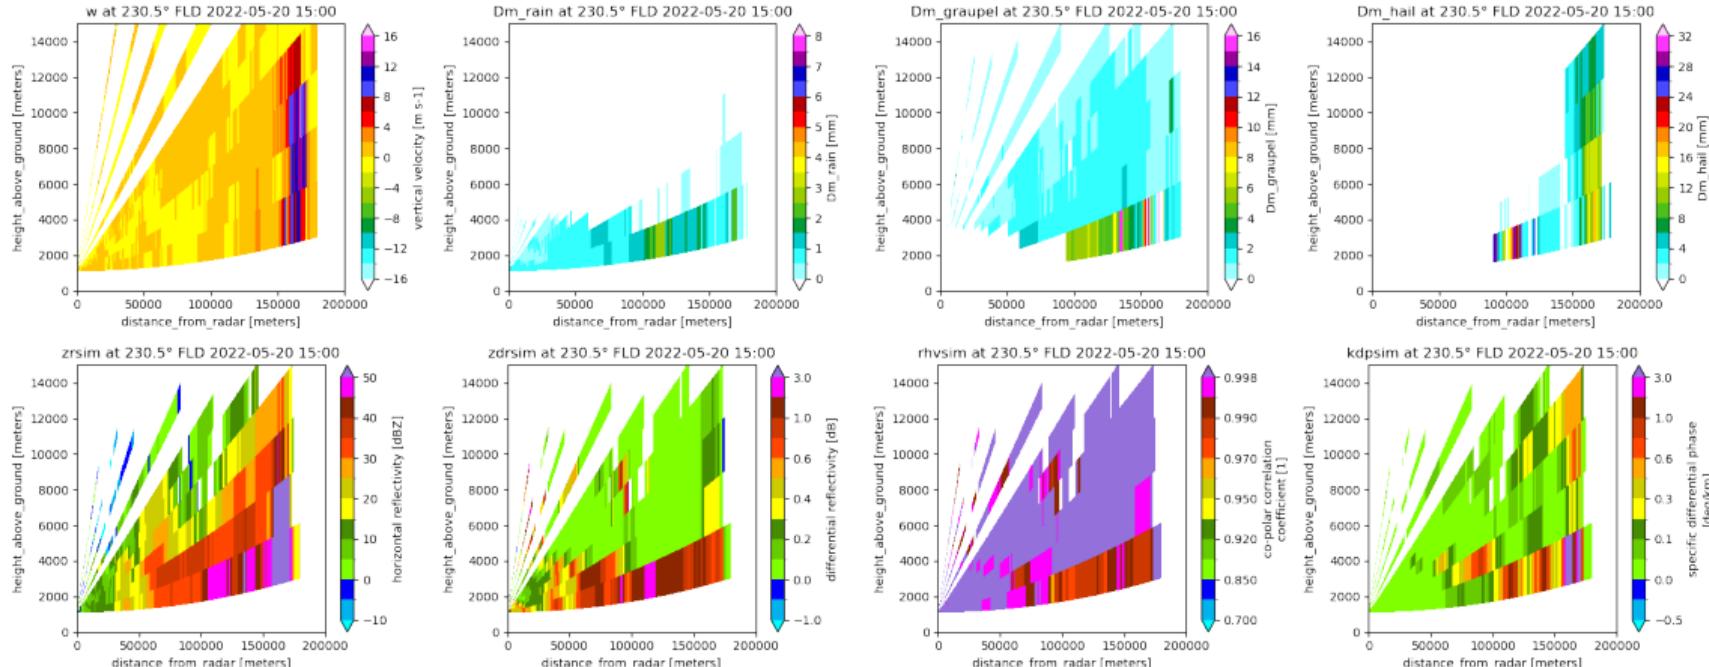

C2: pseudoRHIs (230.5°) with w, qr, qg, qh for FLD on 20-05-2022 15:00

→ core updraft of $w \sim 12 \text{ m/s}$

→ specific contents for rain, graupel, and hail are high but differ: more graupel mass

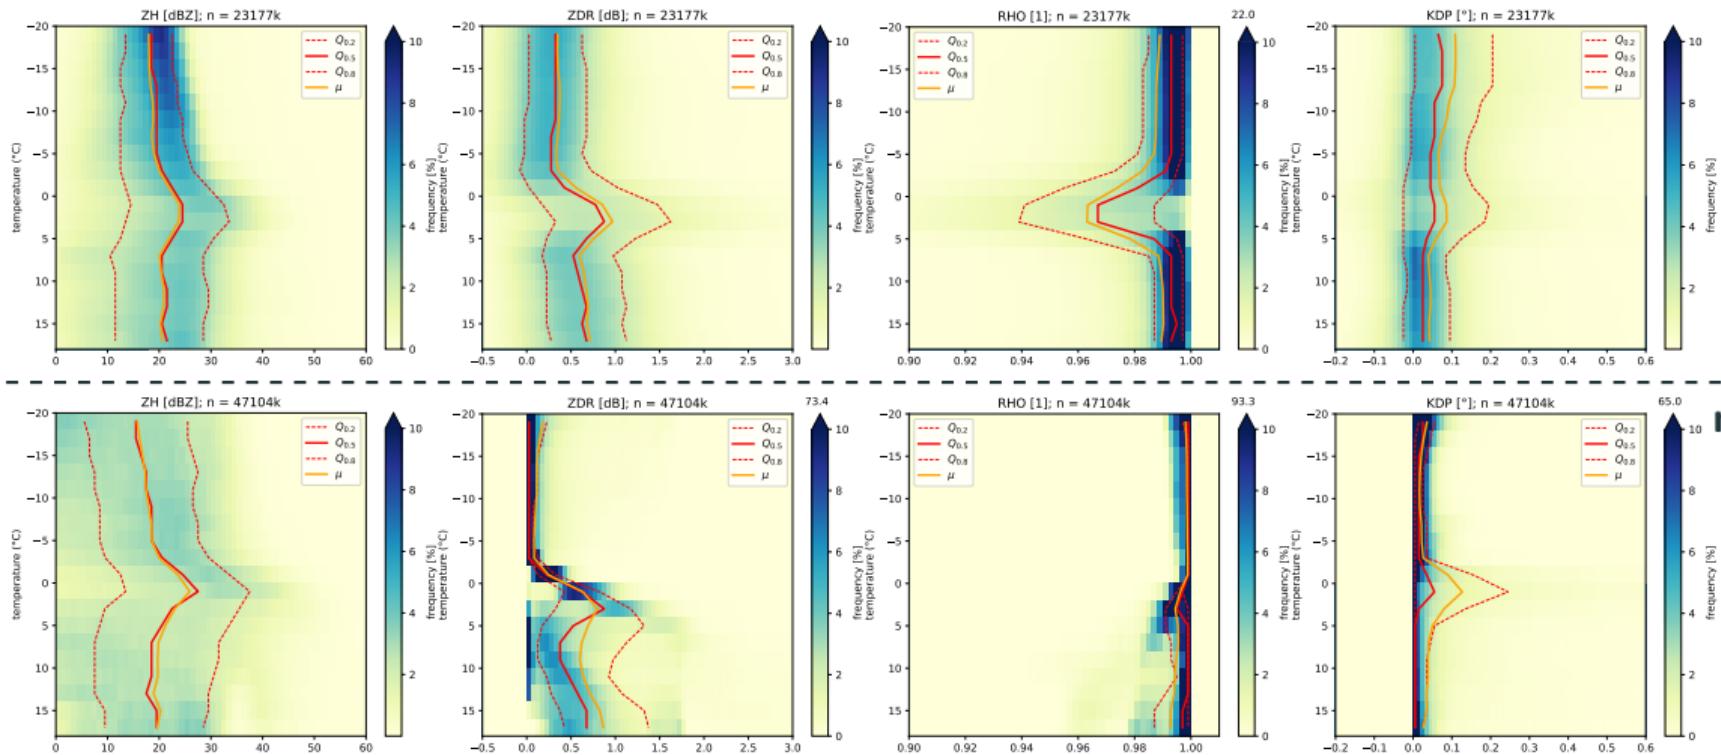

C2: pseudoRHIs (230.5°) with median volume diameters of r, g, and h

→ small raindrops < 0.5 mm
 → bigger hail stones ~ 15 mm dominates signal

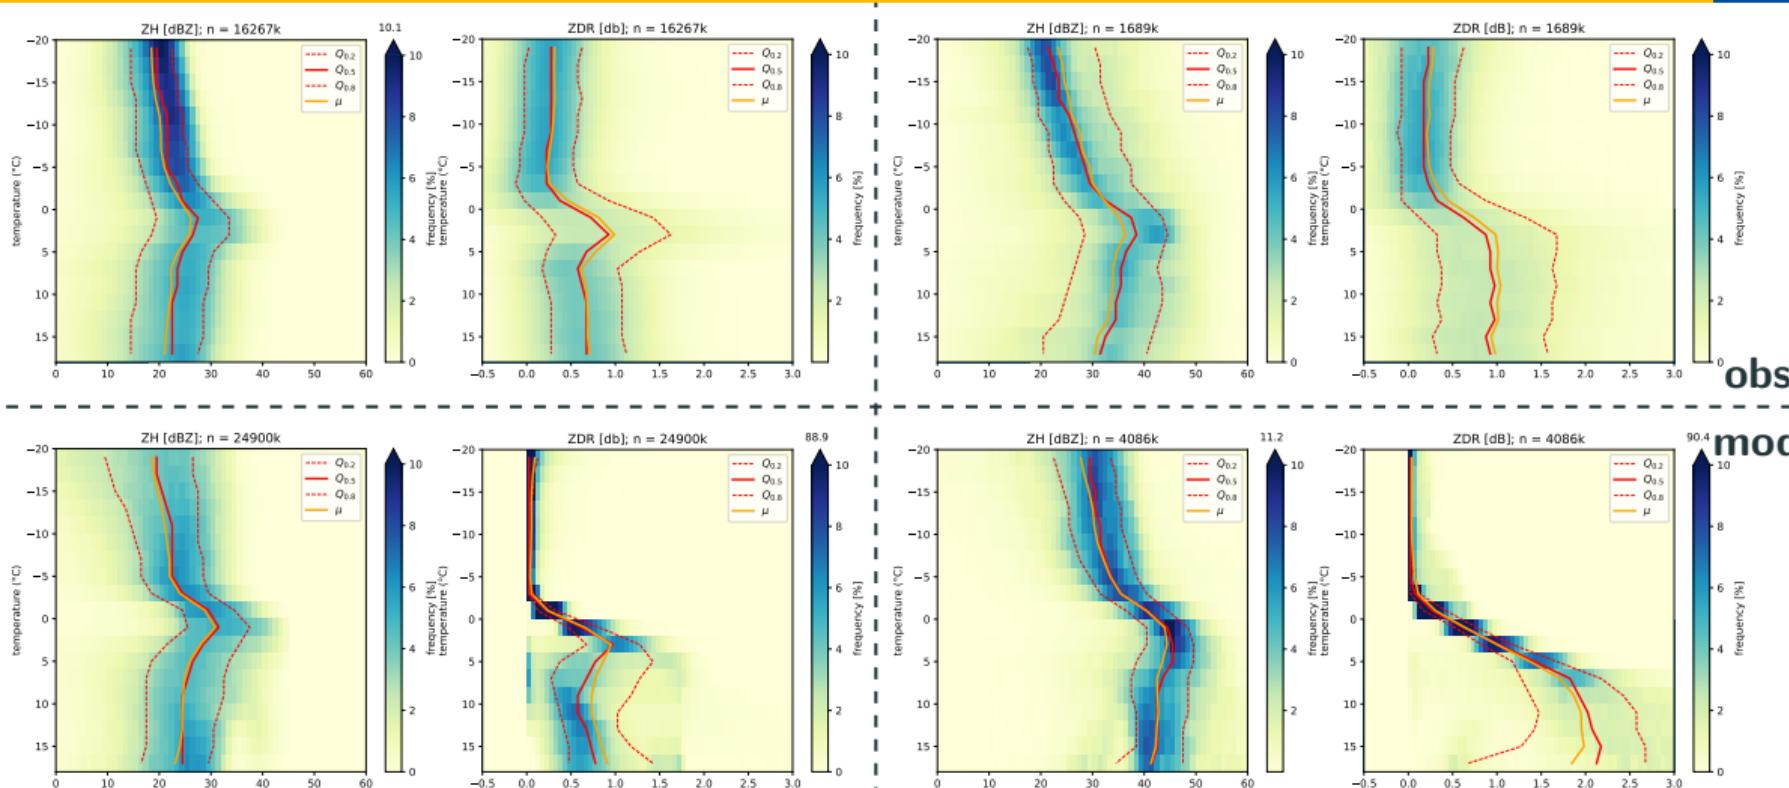

- Z_{DR} -columns are there, however with a weak Z_{DR} signal
 - following two moment scheme produces only small rain drops
 - updrafts generates hail and graupel (quicker than in obs?!)
- ? adjust PSD for rain in convection ?
- ? slow down freezing in updraft ?

CFTDs for FLD on 20-05-2022 (whole day & VOL)

→ limited meaning for the storm areas

CFTDs for FLD on 20-05-2022 (whole VOL and storm area, only Z_H and Z_{DR})

boundary: $25 \leq \max(Z_H) < 45$ in column

storm core: $45 \leq \max(Z_H)$ in column

Conclusion

Conclusion

ICON/EMVORADO is further improved towards

- a more realistic ML
- a better representation of Z_H and Z_{DR} below ML
- showing Z_{DR} -columns

However:

- too high Z_{DR} values in storm cores (below 0°C)
- too low Z_{DR} values in storm cores (above 0°C)
